

#include <array>

array<int, 4> ai = { 1, 2, 3 };

creates the object at that holds four integer values, initializes the first three elements to the values 1, 2, and 3, respectively, and initializes the fourth element to 0.

FIXED SIZE - At compiler from - Con't long to

 Member Functions: std::array offers a rich set of member functions for common array operations, such as:

array_name[index] = value; to provide a meter

- o size(): Returns the size of the array.
- o data(): Returns a pointer to the underlying array elements.
- o front(): Returns a reference to the first element.
- back(): Returns a reference to the last element.
- begin(): Returns an iterator to the beginning of the array.
- o end(): Returns an iterator to the end of the array.
- o empty(): Checks if the array is empty.
- fill(): Fills the array with a specific value.
- swap(): Swaps the contents of two std::array objects.

-> Use Flow 111

by One of the boy problems have is to insert on array here is some applanations

Iterators are a fundamental concept in C++ that provide a way to traverse and manipulate elements within a container. std::array provides begin() and end() methods that return iterators to the first and last elements of the array, respectively. These iterators can be used to iterate through the array elements in a flexible and efficient manner.

Basic Usage:

```
C++
#include <iostream>
#include <orray>
int main() {
    std::arroy<int, 5> numbers = {1, 2, 3, 4, 5};
      // Using iterators to iterate through the array
for (std::array<int, 5>::iterator it = numbers.begin(); it != number
    std::cout << *it << " ";</pre>
    std::cout << std::endl;
                                                                                                            0
Use o código com cuidado.
```

Output:

1 2 3 4 5

Explanation:

- std::array<int, 5::iterator it = numbers.begin(); This line declares an iterator it of type std::array<int, 5::iterator and initializes it to the beginning of the numbers array using the begin() method.
- 2. it != numbers.end()::This condition checks if the iterator it has reached the end of the array using the end() method.

 3. ++it:This statement increments the iterator it to point to the next element in
- the array.
- the array.

 4. std::cout << *it << " "; :This line dereferences the iterator it to get the value of the current element and prints it to the console.

Key Points:

- · Iterators provide a generic and flexible way to traverse different container types in
- std::array 's iterators are specifically designed to work with arrays.
- Iterators can be used with various algorithms from the C++ Standard Template Library (STL) for efficient array manipulation.
- Using iterators can make your code more readable and maintainable.

Additional Notes:

- You can also use reverse iterators (rbegin() and rend()) to iterate through the
- . C++11 introduced range-based for loops, which provide a more concise syntax for iterating through containers like std::array . This is often preferred over using iterators directly.

Vectors class

Willem dynamo ranging - Eliminate the need of manual manary management prevent memory leurs

std::vector increases its size dynamically as needed. This means that you don't have to specify the exact size of the vector upfront, and it can grow or shrink as you add or remove elements.

Here's how the resizing process works:

- Capacity: std::vector maintains an internal capacity, which is the maximum number of elements it can store without reallocating memory.
- Push Back: When you add an element to the vector using push_bock() , the vector checks if its current capacity is sufficient.
- Reallocation: If the capacity is not enough, the vector reallocates memory to
 accommodate the new element. This involves creating a new array with a larger
 capacity, copying the existing elements to the new array, and then releasing the
 old array.
- 4. Growth Factor: The growth factor determines how much the vector's capacity increases when it needs to be reallocated. Typically, the growth factor is a constant value greater than 1, such as 1.5 or 2. This means that the capacity will increase by a certain percentage each time a reallocation is necessary.

Key Points:

- Reallocation can be expensive, especially for large vectors.
- The growth factor can affect the performance of the vector, as a larger growth factor can lead to fewer reallocations but may also waste memory.
- You can use the _reserve() _method to preallocate a specific capacity for the _vector, which can help to reduce the number of reallocations.

1. Creating a std::vector

A std::vector is essentially a dynamic array that automatically resizes as elements are added or removed.

You can also initialize a vector with a specific size and default value:

std::vector(int) numbers(5, 18); // vector of size 5, all elements initia

This of 5 with all elements again 10

2. Adding Elements

You can add elements to a std::vector using the push_back() method, which appends an element to the end of the vector.

cpp

Std::vector<int> numbers;
numbers.push_back(5); // Adds 5 at the end
numbers.push_back(10); // Adds 10 at the end

3. Accessing Elements

You can access elements using the index, just like an array:

The difference between [] and at() is that at() checks bounds and throws an exception if the index is out of range, while [] does not

4. Iterating Through a std::vector

You can use different ways to iterate through a vector:

Range-based for loop (C++11):

```
cpp
for (int num : numbers) {
   std::cout << num << " ";
}</pre>
```

Using iterators: -> Three flot it also mores Love

```
for (std::vector<int>::iterator it = numbers.begin(); it != numbers.end()
std::cout << *it << " ";
}
```

what ideal to grain indefinitly

Yes, you can insert an element in the middle of a std::vector using the insert() method. This method takes two parameters:

- . The iterator pointing to the position where you want to insert the element.
- . The value of the element to insert.

Here's an example:

```
C++

#include <iostream>
#include <vector>
int main() {
    std::vector<int> numbers = {1, 2, 3, 4, 5};

    // Insert the value 100 at index 2 (between 2 and 3)
    numbers.insert(numbers.begin() + 2, 100);

    // Print the vector
    for (int num : numbers) {
        std::cout << num << " ";
    }
    std::cout << std::endl;
    return 0;
}</pre>
```

Output:

melle of 4h

```
1 2 100 3 4 5
```

In this example, the <code>insert()</code> method is used to insert the value 100 at index 2 of the <code>numbers</code> vector. This shifts the elements at index 2 and beyond to the right, making room for the new element.

You can also use the <code>insert()</code> method to insert multiple elements at once. For example:

```
C++
numbers.insert(numbers.begin() + 2, 3, 0);
Use o código com cuidado.
```

This will insert three elements with the value 0 at index 2 of the numbers vector.

4. Iterating Through a std::vector

You can use different ways to iterate through a vector:

Range-based for loop (C++11):

```
cpp

for (int num : numbers) {
   std::cout << num << " ";
}</pre>
```

Using iterators: - The flot et also corres les

5. Removing Elements

You can remove the last element using pop_back():

You can remove specific elements or ranges of elements using erase():

6. Getting Size and Capacity

- size(): Returns the number of elements in the vector.
- capacity(): Returns the amount of space allocated for the vector (it may be greater than the size).

7. Resizing and Clearing

You can resize a vector

And you can clear all elements in the vector:

numbers.insert(numbers.begin() + 2, 3, 0);

Use o código <u>com cuidade</u>.

This will insert three elements with the value O at index 2 of the <code>numbers</code> vector.

Funções

C Expandir a tabela

Nome	Descrição
assign	Apaga um vetor e copia os elementos especificados para o vetor vazio.
at	Retorna uma referência ao elemento em um local especificado no vetor.
back	Retorna uma referência ao último elemento do vetor.
begin	Retorna um iterador de acesso aleatório para o primeiro elemento no vetor.
capacity	Retorna o número de elementos que o vetor pode conter sem alocar mais armazenamento.
cbegin	Retorna um iterador de acesso aleatório const para o primeiro elemento no vetor.
cend	Retorna um iterador de acesso aleatório const que aponta para imediatamente após o fim do vetor.
crbegin	Retorna um iterador const para o primeiro elemento em um vetor invertido.
crend	Retorna um iterador const para o final de um vetor invertido.
clear	Apaga os elementos do vetor.
data	Retorna um ponteiro para o primeiro elemento no vetor.
emplace	Insere um elemento construído no local no vetor em uma posição especificada.
emplace_back	Adiciona um elemento construído no local ao final do vetor.
empty	Testa se o contêiner do vetor está vazio.
end	Retorna um iterador de acesso aleatório que aponta para o final do vetor.
erase	Remove um elemento ou um intervalo de elementos em um vetor das posições especificadas.
front	Retorna uma referência ao primeiro elemento em um vetor.
get_allocator	Retorna um objeto para a classe allocator usada por um vetor.
insert	Insere um elemento ou uma série de elementos no vetor em uma posição especificada.
max_size	Retorna o tamanho máximo do vetor.
pop_back	Exclui o elemento no final do vetor.
push_back	Adiciona um elemento ao final do vetor.
rbegin	Retorna um iterador para o primeiro elemento em um vetor invertido.
rend	Retorna um iterador para o final de um vetor invertido.
reserve	Reserva um tamanho mínimo de armazenamento para um objeto vector.
resize	Especifica um novo tamanho para um vetor.
shrink_to_fit	Descarta o excesso de capacidade.
size	Retorna o número de elementos no vetor.
swap	Troca os elementos de dois vetores.
